

Security

Chapter 15: Security

- ❑ The Security Problem
- ❑ Program Threats
- ❑ System and Network Threats
- ❑ Cryptography as a Security Tool
- ❑ User Authentication
- ❑ Implementing Security Defenses
- ❑ Firewalling to Protect Systems and Networks
- ❑ Computer-Security Classifications
- ❑ An Example: Windows 7

Objectives

- To discuss security threats and attacks
- To explain the fundamentals of encryption, authentication, and hashing
- To examine the uses of cryptography in computing
- To describe the various countermeasures to security attacks

The Security Problem

- System **secure** if resources used and accessed as intended under all circumstances
 - Unachievable
- **Intruders** (**crackers**) attempt to breach security
- **Threat** is potential security violation
- **Attack** is attempt to breach security
- Attack can be accidental or malicious
- Easier to protect against accidental than malicious misuse

Security Violation Categories

- ❑ **Breach of confidentiality**
 - ❑ Unauthorized reading of data
- ❑ **Breach of integrity**
 - ❑ Unauthorized modification of data
- ❑ **Breach of availability**
 - ❑ Unauthorized destruction of data
- ❑ **Theft of service**
 - ❑ Unauthorized use of resources
- ❑ **Denial of service (DOS)**
 - ❑ Prevention of legitimate use

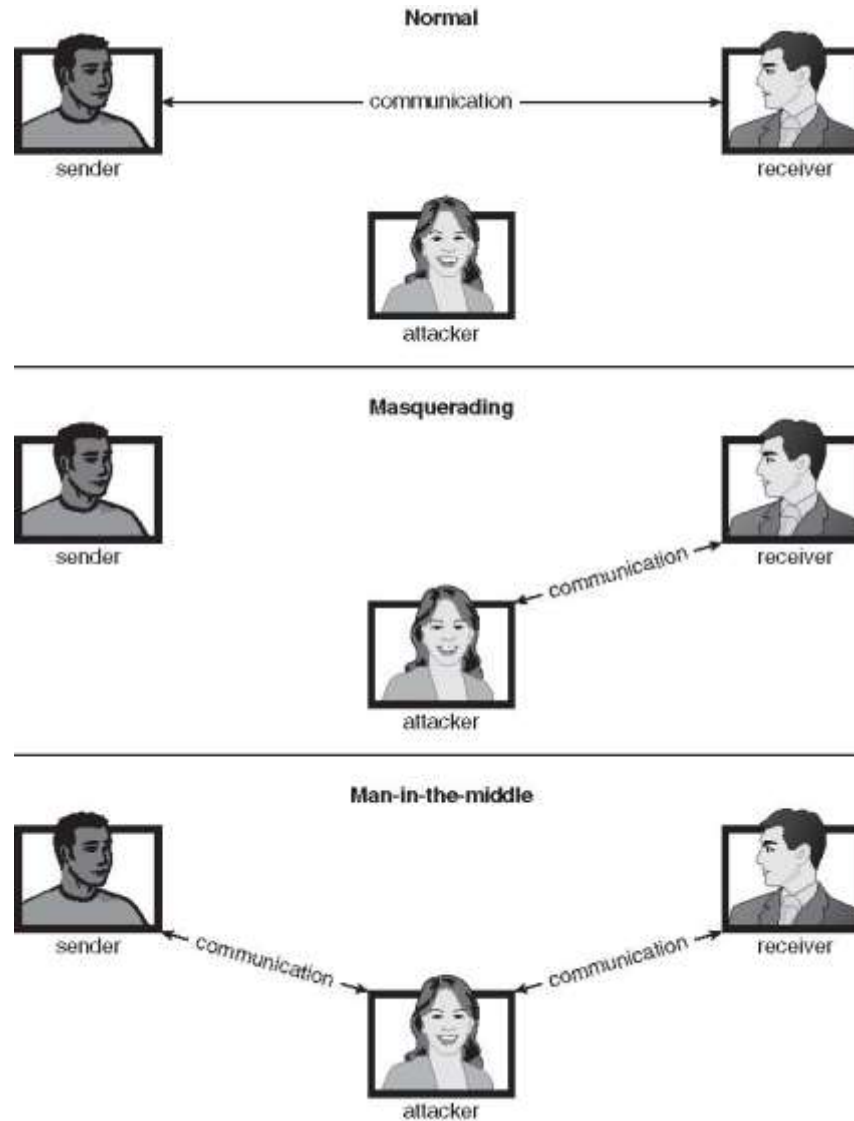

Security Violation Methods

- ❑ **Masquerading** (breach **authentication**)
 - ❑ Pretending to be an authorized user to escalate privileges
- ❑ **Replay attack**
 - ❑ As is or with **message modification**
- ❑ **Man-in-the-middle attack**
 - ❑ Intruder sits in data flow, masquerading as sender to receiver and vice versa
- ❑ **Session hijacking**
 - ❑ Intercept an already-established session to bypass authentication

Standard Security Attacks

Security Measure Levels

- ❑ Impossible to have absolute security, but make cost to perpetrator sufficiently high to deter most intruders
- ❑ Security must occur at four levels to be effective:
 - ❑ **Physical**
 - ▶ Data centers, servers, connected terminals
 - ❑ **Human**
 - ▶ Avoid **social engineering**, **phishing**, **dumpster diving**
 - ❑ **Operating System**
 - ▶ Protection mechanisms, debugging
 - ❑ **Network**
 - ▶ Intercepted communications, interruption, DOS
- ❑ Security is as weak as the weakest link in the chain
- ❑ But can too much security be a problem?

Program Threats

- Many variations, many names
- **Trojan Horse**
 - Code segment that misuses its environment
 - Exploits mechanisms for allowing programs written by users to be executed by other users
 - **Spyware, pop-up browser windows, covert channels**
 - Up to 80% of spam delivered by spyware-infected systems
- **Trap Door**
 - Specific user identifier or password that circumvents normal security procedures
 - Could be included in a compiler
 - How to detect them?

Program Threats (Cont.)

❑ Logic Bomb

- ❑ Program that initiates a security incident under certain circumstances

❑ Stack and Buffer Overflow

- ❑ Exploits a bug in a program (overflow either the stack or memory buffers)
- ❑ Failure to check bounds on inputs, arguments
- ❑ Write past arguments on the stack into the return address on stack
- ❑ When routine returns from call, returns to hacked address
 - ▶ Pointed to code loaded onto stack that executes malicious code
- ❑ Unauthorized user or privilege escalation

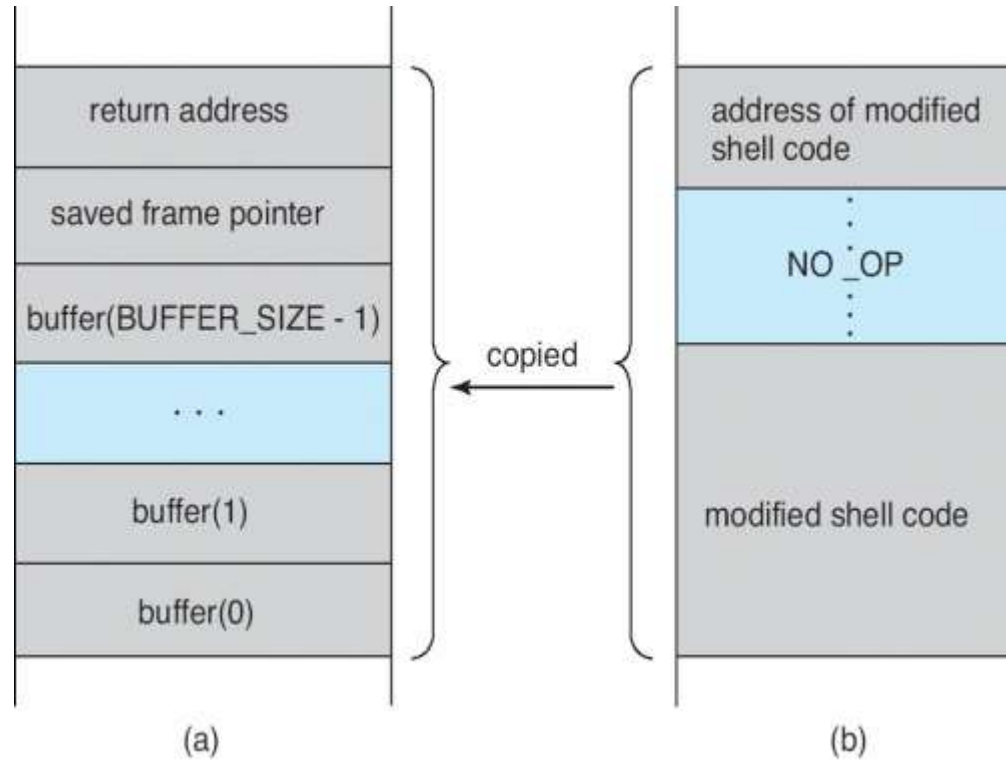

C Program with Buffer-overflow Condition

```
#include <stdio.h>
#define BUFFER SIZE 256
int main(int argc, char *argv[])
{
    char buffer[BUFFER SIZE];
    if (argc < 2)
        return -1;
    else {
        strcpy(buffer, argv[1]);
        return 0;
    }
}
```

Hypothetical Stack Frame

Before attack

After attack

Program Threats (Cont.)

□ Viruses

- Code fragment embedded in legitimate program
- Self-replicating, designed to infect other computers
- Very specific to CPU architecture, operating system, applications
- Usually borne via email or as a macro
- Visual Basic Macro to reformat hard drive

```
Sub AutoOpen()
```

```
Dim oFS
```

```
Set oFS = CreateObject(''Scripting.FileSystemObject'')
```

```
vs = Shell(''c:command.com /k format c:''',vbHide)
```

```
End Sub
```

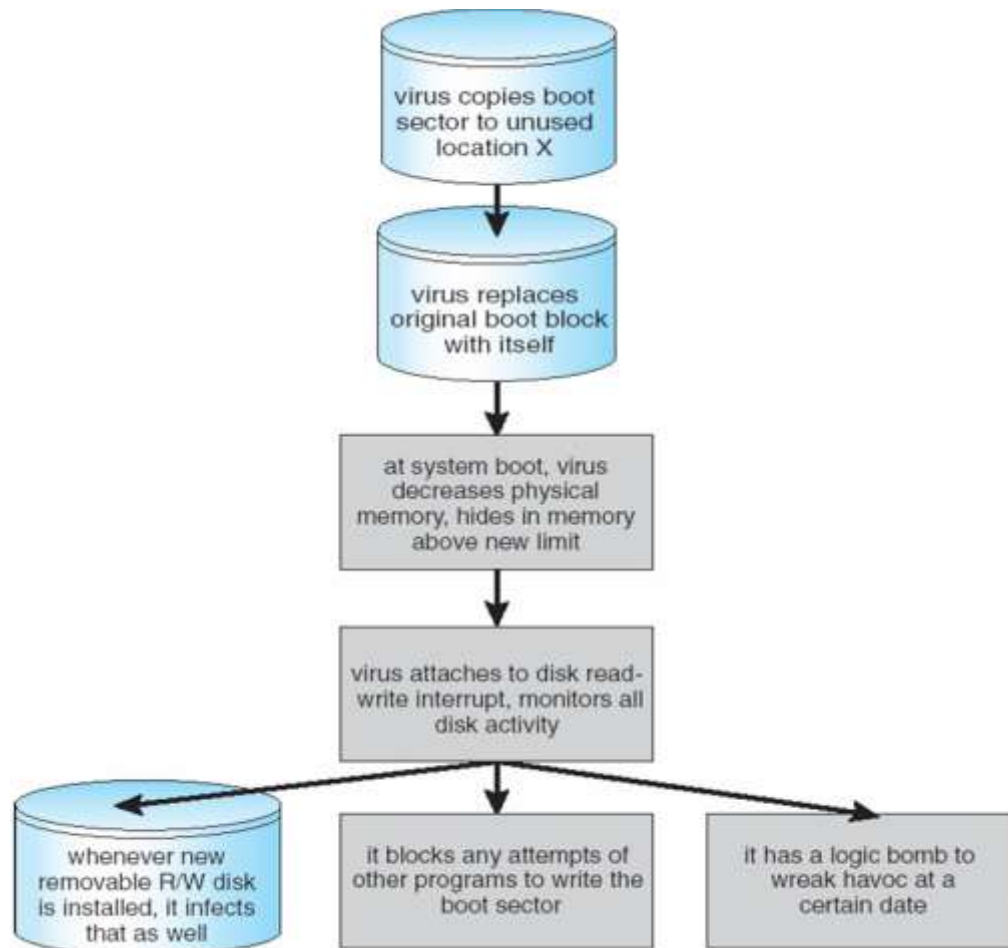

Program Threats (Cont.)

- ❑ **Virus dropper** inserts virus onto the system
- ❑ Many categories of viruses, literally many thousands of viruses
 - ❑ File / parasitic
 - ❑ Boot / memory
 - ❑ Macro
 - ❑ Source code
 - ❑ Polymorphic to avoid having a **virus signature**
 - ❑ Encrypted
 - ❑ Stealth
 - ❑ Tunneling
 - ❑ Multipartite
 - ❑ Armored

A Boot-sector Computer Virus

The Threat Continues

- ❑ Attacks still common, still occurring
- ❑ Attacks moved over time from science experiments to tools of organized crime
 - ❑ Targeting specific companies
 - ❑ Creating botnets to use as tool for spam and DDOS delivery
 - ❑ **Keystroke logger** to grab passwords, credit card numbers
- ❑ Why is Windows the target for most attacks?
 - ❑ Most common
 - ❑ Everyone is an administrator
 - ▶ Licensing required?
 - ❑ **Monoculture** considered harmful

System and Network Threats

- ❑ Some systems “open” rather than **secure by default**
 - ❑ Reduce **attack surface**
 - ❑ But harder to use, more knowledge needed to administer
- ❑ Network threats harder to detect, prevent
 - ❑ Protection systems weaker
 - ❑ More difficult to have a shared secret on which to base access
 - ❑ No physical limits once system attached to internet
 - ▶ Or on network with system attached to internet
 - ❑ Even determining location of connecting system difficult
 - ▶ IP address is only knowledge

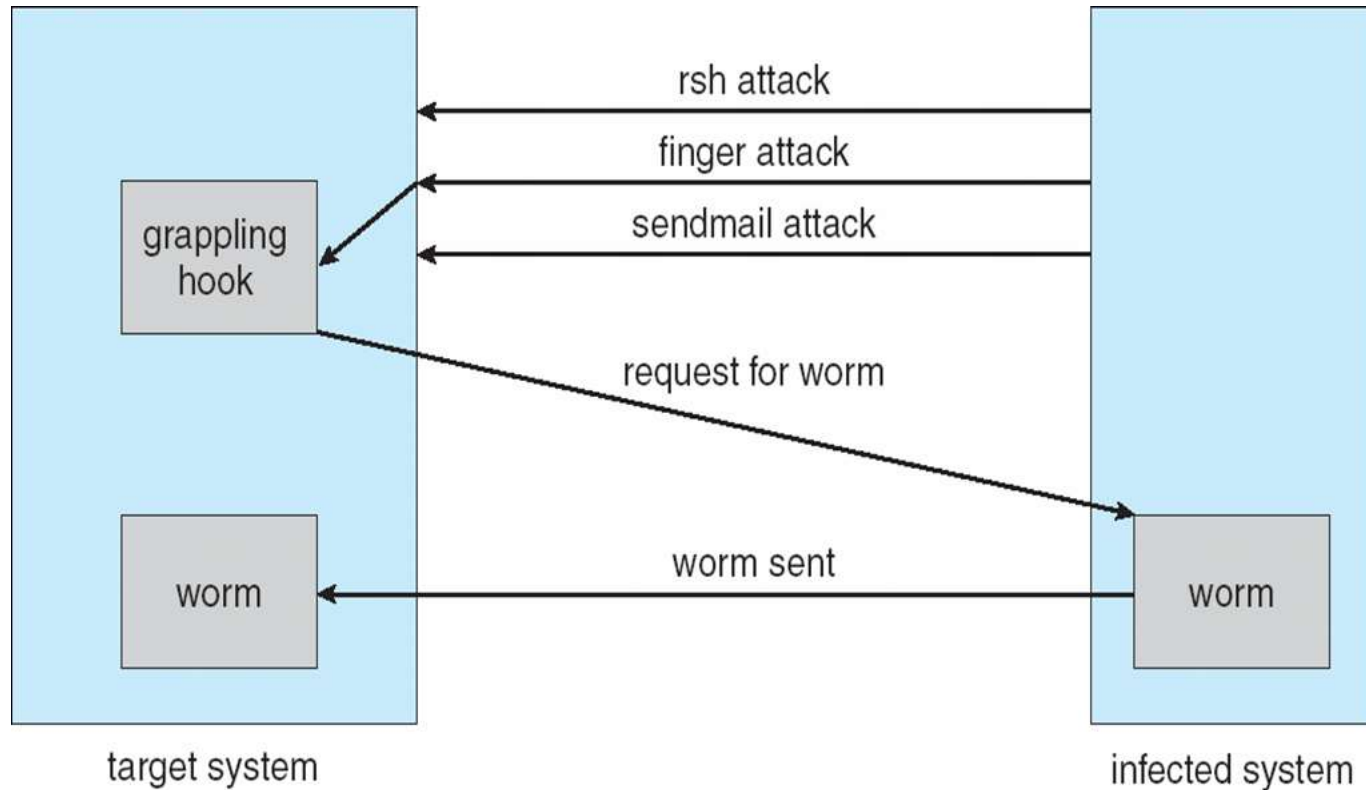

System and Network Threats (Cont.)

- ❑ **Worms** – use **spawn** mechanism; standalone program
- ❑ Internet worm
 - ❑ Exploited UNIX networking features (remote access) and bugs in *finger* and *sendmail* programs
 - ❑ Exploited trust-relationship mechanism used by *rsh* to access friendly systems without use of password
 - ❑ **Grappling hook** program uploaded main worm program
 - ▶ 99 lines of C code
 - ❑ Hooked system then uploaded main code, tried to attack connected systems
 - ❑ Also tried to break into other users accounts on local system via password guessing
 - ❑ If target system already infected, abort, except for every 7th time

The Morris Internet Worm

System and Network Threats (Cont.)

□ Port scanning

- Automated attempt to connect to a range of ports on one or a range of IP addresses
- Detection of answering service protocol
- Detection of OS and version running on system
- `nmap` scans all ports in a given IP range for a response
- `nessus` has a database of protocols and bugs (and exploits) to apply against a system
- Frequently launched from **zombie systems**
 - ▶ To decrease trace-ability

System and Network Threats (Cont.)

❑ Denial of Service

- ❑ Overload the targeted computer preventing it from doing any useful work
- ❑ **Distributed denial-of-service (DDOS)** come from multiple sites at once
- ❑ Consider the start of the IP-connection handshake (SYN)
 - ▶ How many started-connections can the OS handle?
- ❑ Consider traffic to a web site
 - ▶ How can you tell the difference between being a target and being really popular?
- ❑ Accidental – CS students writing bad `fork()` code
- ❑ Purposeful – extortion, punishment

Cryptography as a Security Tool

- Broadest security tool available
 - Internal to a given computer, source and destination of messages can be known and protected
 - ▶ OS creates, manages, protects process IDs, communication ports
 - Source and destination of messages on network cannot be trusted without cryptography
 - ▶ Local network – IP address?
 - Consider unauthorized host added
 - ▶ WAN / Internet – how to establish authenticity
 - Not via IP address

Cryptography

- Means to constrain potential senders (*sources*) and / or receivers (*destinations*) of *messages*
 - Based on secrets (**keys**)
 - Enables
 - ▶ Confirmation of source
 - ▶ Receipt only by certain destination
 - ▶ Trust relationship between sender and receiver

Encryption

- Constrains the set of possible receivers of a message
- **Encryption** algorithm consists of
 - Set K of keys
 - Set M of Messages
 - Set C of ciphertexts (encrypted messages)
 - A function $E: K \rightarrow (M \rightarrow C)$. That is, for each $k \in K$, E_k is a function for generating ciphertexts from messages
 - ▶ Both E and E_k for any k should be efficiently computable functions
 - A function $D: K \rightarrow (C \rightarrow M)$. That is, for each $k \in K$, D_k is a function for generating messages from ciphertexts
 - ▶ Both D and D_k for any k should be efficiently computable functions

Encryption (Cont.)

- An encryption algorithm must provide this essential property: Given a ciphertext $c \in C$, a computer can compute m such that $E_k(m) = c$ only if it possesses k
 - Thus, a computer holding k can decrypt ciphertexts to the plaintexts used to produce them, but a computer not holding k cannot decrypt ciphertexts
 - Since ciphertexts are generally exposed (for example, sent on the network), it is important that it be infeasible to derive k from the ciphertexts

Symmetric Encryption

- ❑ Same key used to encrypt and decrypt
 - ❑ Therefore k must be kept secret
- ❑ DES was most commonly used symmetric block-encryption algorithm (created by US Govt)
 - ❑ Encrypts a block of data at a time
 - ❑ Keys too short so now considered insecure
- ❑ Triple-DES considered more secure
 - ❑ Algorithm used 3 times using 2 or 3 keys
 - ❑ For example $c = E_{k3}(D_{k2}(E_{k1}(m)))$
- ❑ 2001 NIST adopted new block cipher - Advanced Encryption Standard (**AES**)
 - ❑ Keys of 128, 192, or 256 bits, works on 128 bit blocks
- ❑ RC4 is most common symmetric stream cipher, but known to have vulnerabilities
 - ❑ Encrypts/decrypts a stream of bytes (i.e., wireless transmission)
 - ❑ Key is a input to pseudo-random-bit generator
 - ▶ Generates an infinite **keystream**

Asymmetric Encryption

- **Public-key encryption** based on each user having two keys:
 - **public key** – published key used to encrypt data
 - **private key** – key known only to individual user used to decrypt data
- Must be an encryption scheme that can be made public without making it easy to figure out the decryption scheme
 - Most common is **RSA** block cipher
 - Efficient algorithm for testing whether or not a number is prime
 - No efficient algorithm is known for finding the prime factors of a number

User Authentication

- ❑ Crucial to identify user correctly, as protection systems depend on user ID
- ❑ User identity most often established through **passwords**, can be considered a special case of either keys or capabilities
- ❑ Passwords must be kept secret
 - ❑ Frequent change of passwords
 - ❑ History to avoid repeats
 - ❑ Use of “non-guessable” passwords
 - ❑ Log all invalid access attempts (but not the passwords themselves)
 - ❑ Unauthorized transfer
- ❑ Passwords may also either be encrypted or allowed to be used only once
 - ❑ Does encrypting passwords solve the exposure problem?
 - ▶ Might solve **sniffing**
 - ▶ Consider **shoulder surfing**
 - ▶ Consider Trojan horse keystroke logger
 - ▶ How are passwords stored at authenticating site?

Passwords

- ❑ Encrypt to avoid having to keep secret
 - ❑ But keep secret anyway (i.e. Unix uses superuser-only readable file `/etc/shadow`)
 - ❑ Use algorithm easy to compute but difficult to invert
 - ❑ Only encrypted password stored, never decrypted
 - ❑ Add “salt” to avoid the same password being encrypted to the same value
- ❑ One-time passwords
 - ❑ Use a function based on a seed to compute a password, both user and computer
 - ❑ Hardware device / calculator / key fob to generate the password
 - ▶ Changes very frequently
- ❑ Biometrics
 - ❑ Some physical attribute (fingerprint, hand scan)
- ❑ Multi-factor authentication
 - ❑ Need two or more factors for authentication
 - ▶ i.e. USB “dongle”, biometric measure, and password

Implementing Security Defenses

- **Defense in depth** is most common security theory – multiple layers of security
- **Security policy** describes what is being secured
- Vulnerability assessment compares real state of system / network compared to security policy
- Intrusion detection endeavors to detect attempted or successful intrusions
 - **Signature-based** detection spots known bad patterns
 - **Anomaly detection** spots differences from normal behavior
 - ▶ Can detect **zero-day** attacks
 - **False-positives** and **false-negatives** a problem
- Virus protection
 - Searching all programs or programs at execution for known virus patterns
 - Or run in **sandbox** so can't damage system
- Auditing, accounting, and logging of all or specific system or network activities
- Practice **safe computing** – avoid sources of infection, download from only “good” sites, etc

Firewalling to Protect Systems and Networks

- A network **firewall** is placed between trusted and untrusted hosts
 - The firewall limits network access between these two **security domains**
- Can be tunneled or spoofed
 - Tunneling allows disallowed protocol to travel within allowed protocol (i.e., telnet inside of HTTP)
 - Firewall rules typically based on host name or IP address which can be spoofed
- **Personal firewall** is software layer on given host
 - Can monitor / limit traffic to and from the host
- **Application proxy firewall** understands application protocol and can control them (i.e., SMTP)
- **System-call firewall** monitors all important system calls and apply rules to them (i.e., this program can execute that system call)

Network Security Through Domain Separation Via Firewall
